

AI Log for Kavya Patel

Task ID/Title: Debugging Frontend-Backend Integration and Code Review

Purpose of AI Use: Debugging, testing, and code review

Chat Link or Prompt/Response: "How can I check if I have implemented the server in the frontend created by my teammate... tell me if its correct or not:"

AI-Suggested Content:

The AI generated step-by-step terminal commands to test the frontend and backend concurrently without overwriting teammate branches. It diagnosed multiple system errors from terminal screenshots, including Windows PowerShell script execution blocks, missing files from Git branch checkouts, CORS policy rejections requiring a server restart, and a 404 Not Found error due to an overwritten route. Finally, it reviewed the teammate's React component, confirming the fetch API logic was correct but identifying that the email and password state variables were hardcoded.

Validation:

The suggested PowerShell execution policy bypass was run, the missing CORS middleware and deleted POST endpoint were saved to server.js, and the Node server was restarted. The integration was successfully verified by executing a manual fetch test in the browser console. The teammate's UI code was manually reviewed to verify the hardcoded state variables.

Decision:

Accepted and modified before use

Reflection: The AI was highly effective in isolating environmental bugs—such as Git workspace conflicts and PowerShell restrictions—that prevented local testing. The code review successfully caught a critical hardcoded data issue in the React frontend that would have caused the Sprint 1 registration demonstration to fail.
